## Abstract

A series of LaFe<sub>1-x</sub>Ti<sub>x</sub>O<sub>3</sub> (x=0.0, 0.2, 0.4, 0.6 and 0.8) nanoparticles have been successfully synthesized by simple co-precipitation technique. The synthesized samples (calcined at 800° C/3hr) were characterised for structural, optical and magnetic properties. Structural phase formation of the crystal shows orthorhombic planes of these samples phases. The average crystallite size (D<sub>c</sub>) is decreasing with a dopant and found to be varying between ~ 9 - 25 nm. Tailored surface morphology was analyzed using scanning electron microscope (FESEM) and transmission electron microscopes (TEM) with selected area electron diffraction pattern (SAED) also confirms the evolution of orthorhombic phases. Diffuse reflectance spectra (DRS) are recorded to evaluate the variation of optical band gap (E<sub>g</sub>) upon titanium doping into the LaFeO<sub>3</sub> system. The obtained results attributed that E<sub>g</sub> values are increasing with dopant altering between 2.05 - 2.61 eV. The metal oxide (M-O) stretching vibrations and few functional groups are detected from infrared spectra (IR). The weak ferromagnetic behaviour is observed from hysteresis loop behaviour. Additionally, the large hysteresis loop behaviour induces no saturation up to 15 kO<sub>e</sub> in nanoparticles coercivity (H<sub>c</sub>) and anisotropy constants (K<sub>1</sub>) are eventually decreasing with 'x' values.

**Keywords:** Crystallite size; Nanoparticles; Co-precipitation method; Magnetic Properties, Coercivity.

## 1. Introduction

The magnetic nanomaterial is a promising candidate material, due to co-existing states of multiple coupled such as magnetism and superconductivity [1-9]. Lanthanum iron oxide ( $\text{LaFeO}_3$ ) is an  $\text{ABO}_3$  perovskite oxide having an orthorhombic structure [10-13]. It has attracted attention for distinct applications such as electrode materials for fuel cells, photocatalyst, chemical sensors, non-volatile magnetic memory devices and ultrasensitive magnetic read heads of modern hard disk drives, etc. [14–21].

Recently,  $\text{LaFeO}_3$  (LFO) has got much attention owing to its multiferroicity [22]. It is a G-type antiferromagnetic material possessing high Neel temperature ( $T_N$ ) of  $480^\circ\text{C}$ . Also shows a ferroelectric transition at  $200^\circ\text{C}$  [21, 22]. Orthoferrites are the weak ferromagnetic materials with interesting magneto-optical properties [23, 24]. The magnetic structure is illustrated by two face centred cubic sub-lattices. In this structure, each ferric ion ( $\text{Fe}^{3+}$ ) is surrounded by six oxygen ions ( $\text{O}^{2-}$ ) attributing a collinear arrangement of A and B-lattices. It gives rise to antiferromagnetic ordering. However,  $\text{BO}_6$  octahedra are tilted to different degrees based on the diameter of the cation at A-site and show a net magnetic moment [25, 26]. Nano-sized LFO exhibits higher specific surface area (S) than its bulk counterpart, due to quantum size effect [21]. It allows various dopants to accommodate in its structure and therefore, the properties can be tuned based on the kind of dopant [27]. Preferential occupation of A-site or B-sites by the doping element can also influence the electrical, optical and magnetic properties of LFO up to some extent [28]. In the literature, no detailed report is available on the optical and magnetic properties of substitution on B site by Ti ions using co-precipitation method. Hence, Nanocrystalline  $\text{LaFe}_{1-x}\text{Ti}_x\text{O}_3$  powders have been prepared for

investigating structural, optical and magnetic properties using X-ray diffraction (XRD), energy dispersive X-ray analysis (EDX), transmission electron microscopy (TEM), UV-Visible spectrometer, Fourier transform infrared (FT-IR) spectrometer and vibrating sample magnetometer (VSM) respectively.

## 2. Experimental procedure:

$\text{LaFe}_{1-x}\text{Ti}_x\text{O}_3$  ( $x = 0.2, 0.4, 0.6 \text{ \& } 0.8$ ) ceramic powders are prepared by Co-precipitation method with the aqueous solutions of  $\text{La}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O}$  (99.6 % purity, Sigma-Aldrich),  $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  (99.6 % purity, Sigma-Aldrich) and Titanium (IV) isopropoxide (99.6 % purity, Sigma-Aldrich) mixtures respectively in alkaline medium. The solutions of  $\text{La}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O}$ ,  $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  and Titanium (IV) isopropoxide in their stoichiometry (1g of  $\text{La}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O}$  in 50 ml), (0.8g of  $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  in 50 ml), (0.2g of titanium (IV) isopropoxide in 50 ml) were dissolved in double distilled water with a constant stirring. The neutralization is carried out by adding the NaOH solution, and the pH is maintained around at 10. The precipitation is formed when the solution continued stirring for 3 hrs at 80 °C; then the resultant precipitate is cooled to ambient temperature. To remove the additional compounds of sodium and chloride, the precipitate is washed and filtered several times with double distilled water. To remove the water molecules, the precipitate was dried at 100 °C for 12 hrs. The dried sample was fluffy mass in appearance that is grinded for 2 hrs using the motor pestle apparatus and the resulting powder was sintered for 3hrs at 800 °C. After sintering, the sample was once again grinded for 4 hrs to make uniform particle size. The resultant powder is subjected to XRD (Bruker X-Ray Powder Diffraction Meter,  $\text{Cu}_{K\alpha}$   $\lambda=0.15418$  nm), SEM/EDAX (SEM with EDX using Carl Zeiss SUPRA- 555), JASCO UV-Visible spectrophotometer (V-670 PC), FT-IR spectrophotometer (IR affinity-1, Shimadzu),

TEM (TEM: Model Tecnai G20, FEI, USA) and VSM (EV-7 VSM with Max. applied field 15 kOe) characterization.

### 3. Results and Discussion

#### 3.1. Structural analysis

Figure 1 depicts the diffraction patterns of  $\text{LaFe}_{1-x}\text{Ti}_x\text{O}_3$  (LFTO) nanoparticles. All the reflection planes are in good agreement with the standard JCPDS: 82-1958 of orthorhombic LFO. Few secondary phases (preceded by \*) corresponding to  $\text{La}_2\text{TiO}_5$  are detected for the increased titanium concentrations ( $x=0.6 - 0.8$ ).

Fig. 1. XRD pattern of  $\text{LaFe}_{1-x}\text{Ti}_x\text{O}_3$  ( $x = 0.2, 0.4, 0.6$  &  $0.8$ )

The average diameter (D) of the sample is evaluated for the intense peak positions using Scherrer's formula [29]:

$$D = \frac{k\lambda}{\beta \cos \theta} \text{-----(1)}$$

Where 'k' is a constant and is approximate equals to 0.9 for a spherical symmetry, 'λ' is X-ray wavelength of  $\text{Cu}_{K\alpha} = 1.5418 \text{ \AA}$ , 'θ' is diffraction angle and 'β' is full-width half maxima (FWHM).

The established results revealed that the crystallite size is decreasing with the increase of Ti content and found to be varying between ~ 9 - 26 nm. Respectively, similar kind of trend was reported [21]. This behaviour is attributed owing to weakening crystal growth or an increase of elastic strain ( $\varepsilon = \beta/4\tan\theta$ ) by Ti-addition. From Table 1, it is evident that ε –value is increasing from  $35 \times 10^{-4}$  to  $26 \times 10^{-3}$ . The lattice constants (a, b &c) calculated using the

formula:

$$\frac{1}{d^2} = \frac{h^2}{a^2} + \frac{k^2}{b^2} + \frac{l^2}{c^2} \text{-----(2)}$$

Where 'd' is interplanar spacing distances and hkl are the Miller indices. These are computed using X-powder -12 software. The obtained data is shown in Table 1. A small change of unit cell volume ( $V = abc$ ) is noticed with titanium addition (Table 1). Iron possible vacancies are  $\text{Fe}^{2+}$ ,  $\text{Fe}^{3+}$ , and  $\text{Fe}^{+4}$ . To ensure the charge neutrality and stable orthorhombic structure,  $\text{Fe}^{4+}$  ions should necessarily be formed in the lattice structure because of +4 valence of titanium. Hence, it removes ferric ions incorporating excess oxygen ions. Lanthanum ions preferentially occupy A-site while iron ions occupy B-site in LFO structure. Upon  $\text{Ti}^{4+}$  doping, it replaces  $\text{Fe}^{4+}$  ions. The ionic radii of  $\text{La}^{3+}$  (0.136 nm),  $\text{Fe}^{4+}$  (0.058nm),  $\text{Ti}^{4+}$  ions (0.061nm) and  $\text{O}^{2-}$  (0.155 nm) are responsible for various structural parameters such as tolerance factors (t), lattice constants and X-ray density ( $D_x$ ) [21]. It is remembered that perovskite materials perform a stable structure depending upon their tolerance factor (t) and

is mathematically given by

$$t = \frac{R_A + R_B}{\sqrt{2[R_B + R_0]}} + \frac{k^2}{b^2} + \frac{l^2}{c^2} \text{-----(3)}$$

Where  $R_A$ ,  $R_B$  and  $R_O$  are ionic radii of A-site, B-site and oxygen ions respectively. For a stable orthorhombic structure  $t < 0.96$  [30]. In this investigation  $t$ -values for  $[La^{3+}]_A[Fe^{4+}, Ti^{4+}]_BO_2$  structure are 0.645 & 0.644(<0.96) with respect to Ti and Fe-ions at B-sites respectively. The high phase purity (absence of secondary phases) at  $x = 0$  & 0.2 shows an increasing trend of lattice constants (Table 1).

Table 1. Structural parameters of  $LaFe_{1-x}Ti_xO_3$  ( $x = 0.2, 0.4, 0.6$  &  $0.8$ )

X	0	0.2	0.4	0.6	0.8
D(nm)	24.6	15.3	11	10	9
FWHM( $\beta$ )	0.005	0.012	0.019	0.013	0.022
Strain ( $\epsilon$ )	0.003	0.007	0.010	0.022	0.026
a( $\text{\AA}$ )	5.513	5.608	5.534	5.587	5.640
b( $\text{\AA}$ )	5.473	5.621	5.572	5.520	5.714
c( $\text{\AA}$ )	7.819	7.911	7.850	7.860	7.931
V ( $\text{\AA}^3$ )	235.9	249.3	242.1	242.4	255.6
$D_x(\text{g/cm}^3)$	6.833	6.424	6.573	6.521	6.183
S ( $\text{m}^2/\text{g}$ )	35.7	61.1	82.9	92.0	107.8
$\text{vcm}^{-1}(\text{M-O})$	538.1	540.1	551.6	555.5	561.9

Since  $Ti^{4+}$  ( $0.61\text{\AA}$ ) ionic radius is greater than that of  $Fe^{4+}$  ( $0.58\text{\AA}$ ). On the other hand for  $x = 0.3-0.8$ , a unsystematic variation of lattice constants is noticed due to the presence of secondary phases. The X-ray density ( $D_x$ ) and specific surface area (S) are calculated by following relations [30].

$$D = \frac{ZM}{Na^3} \text{-----(4)} \quad S = \frac{6000}{D * D_x} \text{-----(5)}$$

Where  $Z$  (4) is a number of atoms per unit cell,  $M$  is the molecular weight and  $N$  ( $6.023 \times 10^{23}$ ) is the Avogadro's number. In respect of the results (Table 1), at increased doping level,  $D_x$  is exhibiting unsystematic trend due to presence of secondary phases. The surface area is increasing with rising  $x$ -value from  $35.7 \text{ m}^2.\text{g}^{-1}$  to  $107.8 \text{ m}^2.\text{g}^{-1}$  owing to decrease of crystallite size. This clearly reveals the fact that secondary phases can affect the dimensions, volume of unit cell and density.

### 3.2 Surface Morphology

Surface morphology and elemental analysis of nanoparticles are carried out using scanning electron microscope (SEM) and energy dispersive x-ray analysis (EDAX). In SEM photographs (Fig. 2) show the particle grain size around 39 – 77 nm grains were detected. This confirms the formation of well nanocrystalline grains during the heat treatment. As far as the shape is concerned,  $x = 0$  & 0.2 showed the flat plate-like grains. However, for the rest compositions almost clustered spherical grains are observed. It is also noticed that the obtained grain sizes (39 – 77 nm) are approximately identical to the crystallite size (25 - 9 nm) established from diffraction studies. The small enhancement of grain size is due to creeping of grain boundary when the specimen underwent heat treatment. The EDAX spectra show the abundance of elements in the nanopowders and are presented in Fig. 3. The presence of La, Fe, Ti and O elements including their atomic (At%) and weight (Wt%) percentages are reported (inset table of EDAX).

Fig. 2 SEM photographs of  $\text{LaFe}_{1-x}\text{Ti}_x\text{O}_3$  ( $x = 0, 0.2, 0.4, 0.6$  &  $0.8$ )

Fig . 3 EDAX spectra of  $\text{LaFe}_{1-x}\text{Ti}_x\text{O}_3$  ( $x = 0$  &  $0.2$ )

The surface morphology and structure of LFTO is investigated by TEM and selected area electron diffraction (SAED) patterns respectively (Fig. 4). TEM photograph ( $x = 0.2$ ) shows a small agglomeration among the nanoparticles. This is due to weak magnetic interactions between the particles [17]. The average grain size of 31.4 nm is consistent with the diffraction and SEM results. The SAED pattern shows concentric circular pattern attributing the polycrystalline structure and is very close to the diffraction pattern of XRD ( $x = 0.2$ ). The SAED pattern lengths are shown in Fig. 4.

Fig. 4. TEM images of  $\text{LaFe}_{0.8}\text{Ti}_{0.2}\text{O}_3$

### 3.3 FTIR analysis

Fig. 5 represents the Fourier transform infrared spectra (FT-IR) of  $\text{La}_{1-x}\text{Ti}_x\text{FeO}_3$  ( $x = 0, 0.2, 0.4, 0.6 \text{ \& } 0.8$ ) nano-powders. All spectra show broad absorption bands around  $540 - 560 \text{ cm}^{-1}$ . A small shift is identified for metal-oxide (M-O) towards the higher wave numbers i.e. from  $538.1 - 561.9 \text{ cm}^{-1}$ . Some more absorption bands are observed at approximately  $3618.8 \text{ cm}^{-1}$  and  $3454.9 \text{ cm}^{-1}$  which are designed to the symmetric and asymmetric stretching modes of water molecules [31]. At approximately  $1456.3 \text{ cm}^{-1}$  and  $1687.9 \text{ cm}^{-1}$  wave numbers, the bending modes of the O-H bond are observed. A small absorption peak at  $854.5 \text{ cm}^{-1}$  reveals the presence of metal oxide-bonds which are assigned to the vibrations of Fe-O and O-Fe-O bonds [32].

Fig.5 FTIR spectra of  $\text{LaFe}_{1-x}\text{Ti}_x\text{O}_3$  ( $x = 0, 0.2, 0.4, 0.6$  &  $0.8$ )

### 3.4 UV-Visible absorption spectra

UV–Visible spectroscopy is employed to characterise the optical properties of the LFTO nanoparticles. The direct band gap energy ( $E_g$ ) was determined by fitting the absorption data to the direct transition as the equation is  $\alpha h\nu = A (h\nu - E_g)^{1/2}$ , where  $\alpha$  is the optical absorption coefficient,  $h\nu$  is the photon energy,  $E_g$  is the direct band gap, and  $A$  is constant. The extrapolation of the linear parts of the curves toward absorption equal to zero gives  $E_g$  for direct transitions (Fig. 6). The estimated direct band gaps of all samples are in the range of 2.05, 2.15, 2.39, 2.45 and 2.61 eV [30]. The results are in consistent with the reported direct bandgap value of  $\text{LaFeO}_3$  nanoparticles synthesised by sol–gel auto-combustion method is 2.1 eV [34–36]. These small band gaps of  $\text{LaFeO}_3$  are interesting for application in photocatalytic [37].

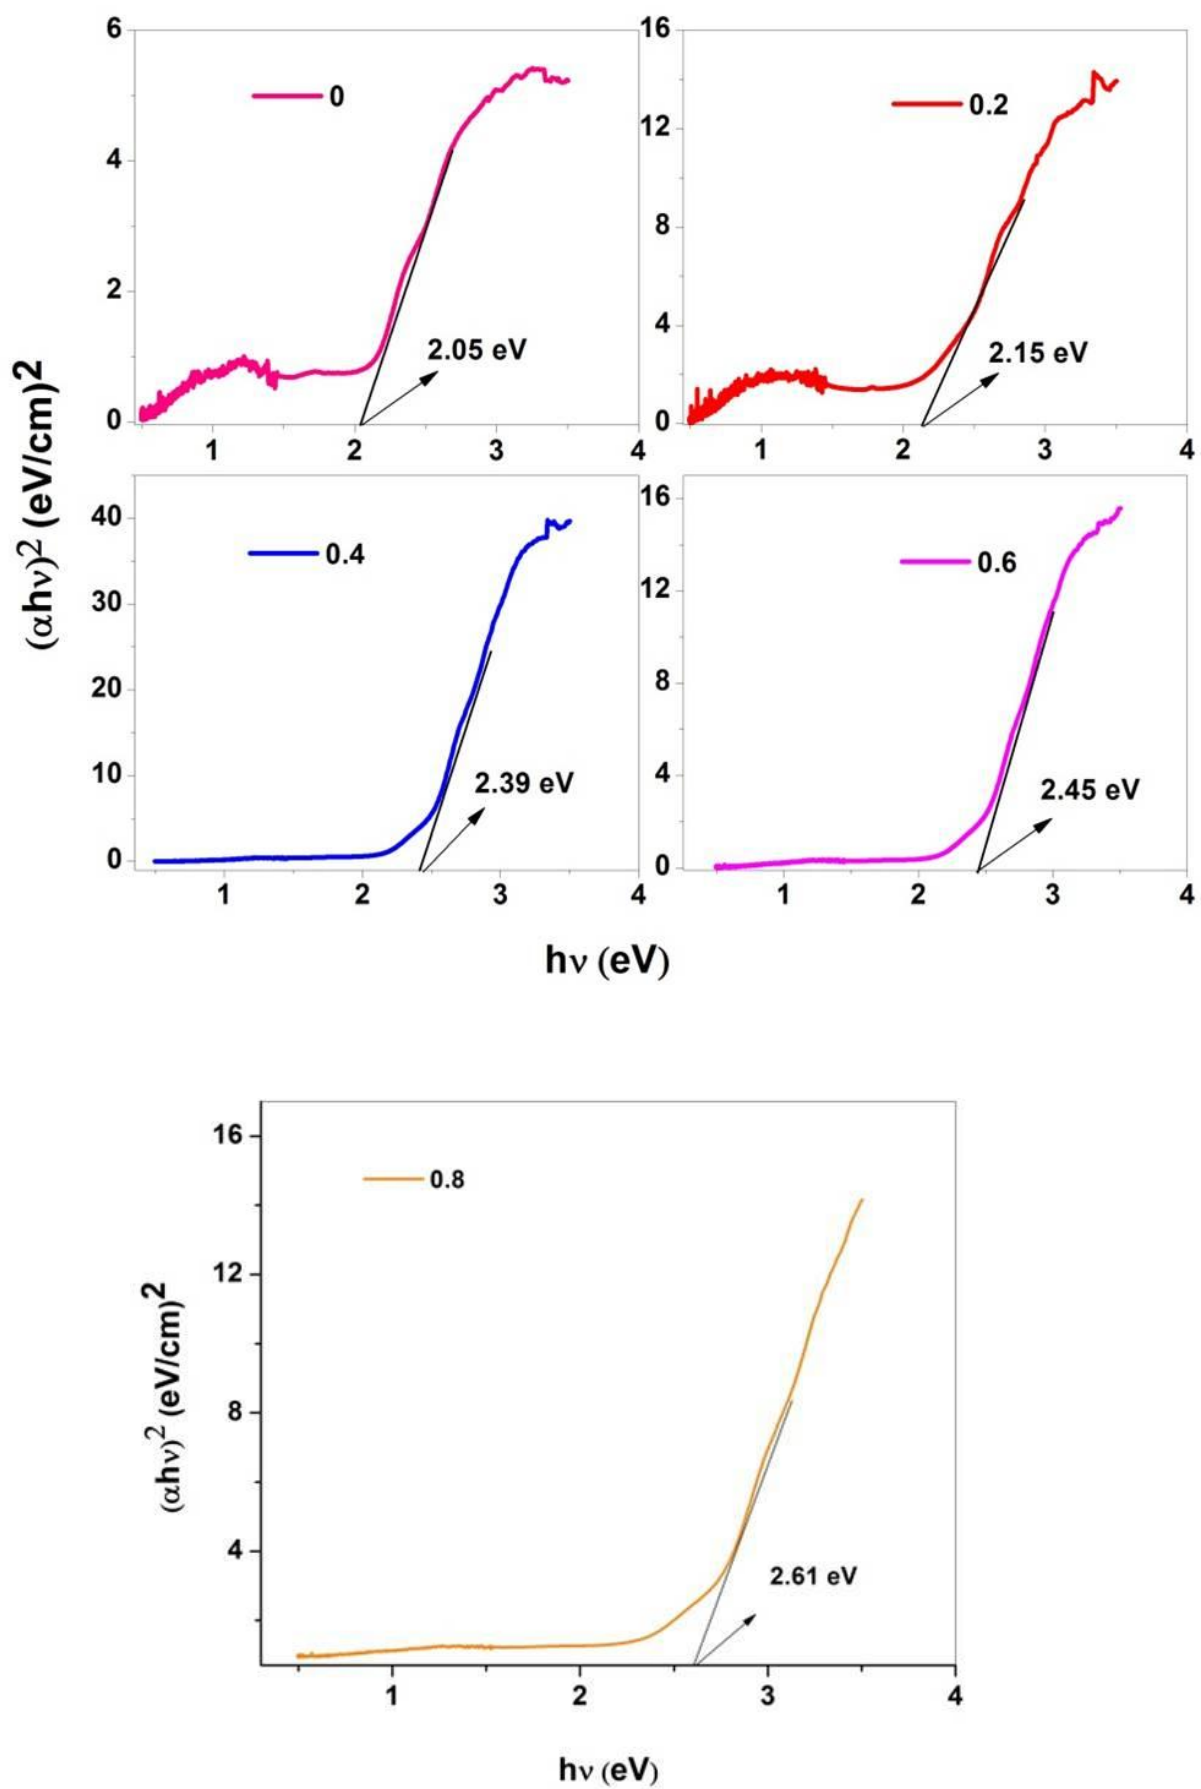

Fig. 6. UV-Visible spectra of  $\text{LaFe}_{1-x}\text{Ti}_x\text{O}_3$  ( $x = 0, 0.2, 0.4, 0.6 \text{ \& } 0.8$ )

### 3.5 VSM analysis

The M-H loop behavior of  $\text{LaFe}_{1-x}\text{Ti}_x\text{O}_3$  ( $x = 0, 0.2, 0.4, 0.6$  &  $0.8$ ) is studied from vibrating sample magnetometer at room temperature (RT) varying the applied magnetic field ( $H$ ) during the range of  $0$  to  $\pm 15$  kOe (Fig. 8). From hysteresis loop behaviour it is confirmed that the nanopowders exhibit weak ferromagnetic nature having a small M-H loop. This may be due to spin-canted iron moments generated from disordered surface spins [21]. The magnetic parameters are reported in Table 2. It can be seen from the table that magnetisation ( $M_s$ ), magnetic moment ( $n_B$ ), remanence ( $M_r$ ) and squareness are increasing from  $x = 0$ - $0.2$ . For further increase of  $x$ - value both the parameters are showing a decreasing trend. The attained maximum value of all magnetic parameters other than coercivity ( $H_c$ ) and anisotropy constant ( $K_1$ ) is interesting for  $x = 0.2$ . High phase purity and an increasing number of uncompensated spins of iron moments, in turn, causes it. Since they can allow the domain wall motion freely; this improves  $n_B$  value. Likewise, the presence of secondary phases and high concentration of non-magnetic cations ( $\text{Ti}^{4+}$ ) can hide the domain wall motion. Thus lowers the values of above mentioned magnetic parameters. It is also found that the anisotropy constant and coercivity are decreasing with the increase of non-magnetic cations. This reveals a proportional relationship between  $H_c$  and  $K_1$ . Normally, coercivity is a crystallite size dependent parameter. At  $x=0.8$ , magnetisation decreases owing to a high AFM spin alignments of  $\text{Fe}^{3+}-\text{O}^{2-}-\text{Fe}^{3+}$  &  $\text{Fe}^{4+}-\text{O}^{2-}-\text{Fe}^{4+}$  by superexchange interaction. This leads to a reduction of magnetisation. At  $x = 0.2$  the maximum value of magnetisation shows magnetic memory device applications.

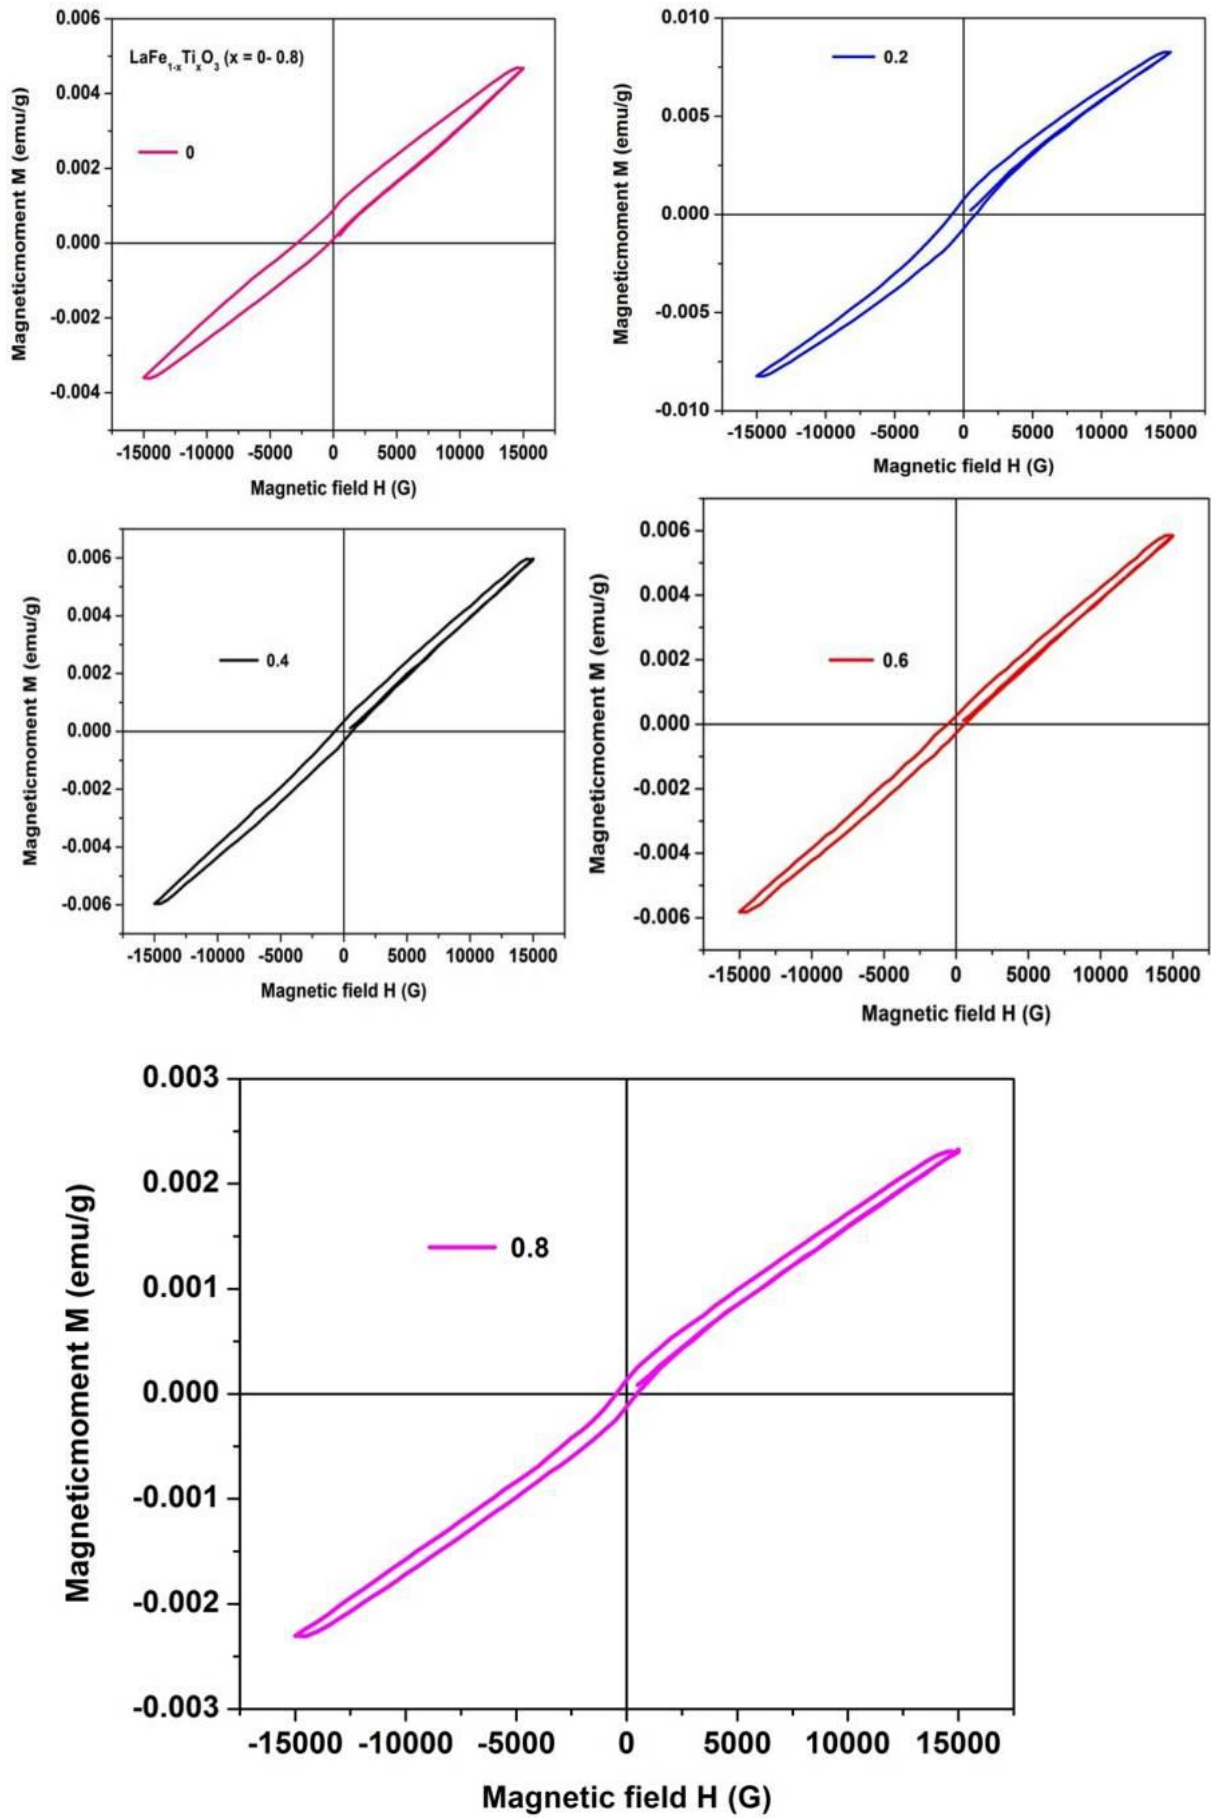

Fig. 7. VSM analysis of  $\text{LaFe}_{1-x}\text{Ti}_x\text{O}_3$  ( $x = 0, 0.2, 0.4, 0.6 \text{ \& } 0.8$ )

From Fig. 8, it is obvious that the coercivity is decreasing with the increase of x-value due to a decrease in crystallite size ( $D_c$ ). Several researchers have reported the inverse relation of  $H_c$  and  $D_c$  based on domain theory [39]. However, in this investigation, a proportional relation is established. According to Stoner-Wohlfarth model [39], for a weak ferromagnetic single domain particle,  $H_c$  decreases as the particle size decreases due to a decrease of magnetic moment and anisotropy constant [40-43].

Figure.8. A graphical representation of dopant vs. coercivity and grain size of the nanopowders

Table: 2 Magnetic properties of Ti-doped LaFeO<sub>x</sub>

X	0	0.2	0.4	0.6	0.8
Coercivity H <sub>c</sub> (G)	1217.6	855.0	683.5	583.6	462.5

#### 4. Conclusion

Nanoparticles of LaFe<sub>1-x</sub>Ti<sub>x</sub>O<sub>3</sub> (x = 0, 0.2, 0.4, 0.6, 0.8) have been prepared by Co-precipitation method. The average crystallite size (D<sub>c</sub>) is varying between 9nm-24.6nm. The morphology is analysed using scanning electron microscope and transmission electron microscope. The E<sub>g</sub> values are increasing with dopant from 2.05 eV to 2.61 eV. The weak ferromagnetic behaviour is observed from hysteresis loop behaviour. Coercivity (H<sub>c</sub>) and anisotropy constants (K<sub>1</sub>) are eventually decreasing with 'x' value. At x = 0.2 the maximum value of magnetisation shows magnetic memory device applications.
